ABSTRACT
This paper presents a novel 3D point cloud gesture recognition system, based on an existing low-cost, accurate and easy to implement 2D point cloud gesture recognition system called $P$. Our work improves recognition rates and lowers algorithmic complexity. We develop new 3D gestures, such as the GUN gesture and the SHAKE gesture, while also developing 3D poses like the L pose, OK pose, ROCK pose and PEACE pose for the LeapMotion Device. We demonstrate proposed gesture and pose methods on various 3D environments including a Monsoon mini-game, a cave painting interaction and a target practice scene. The average recognition rates for 3D gestures and poses were compared against the 2D, 3D and 3D+ recognition systems. The results indicate that most gestures in the proposed system were improved in comparison to the existing ones.

Keywords
User Interaction, Gesture Recognition, Finger Interaction, Leap Motion, 3D Point Cloud.

1. INTRODUCTION
Gesture recognition refers to determining when a gesture has occurred and to the general process of determining when a gesture has started and stopped [Yin14]. Natural gestures can be grouped into manipulative and communicative gestures. Manipulative gestures are about moving or interacting with objects, such as pressing a button or rotating an object around, while communicative gestures have the intent of conveying information to others. Communicative gestures can be an interpretation or movement via a symbol or via an act. A gesture via a symbol is often conveyed with a static hand pose and a gesture via an act is determined by the movement of the hand itself.

While natural gestures work in the real world, determining when the user is making a gesture requires our computer implementation to take on a more structured approach of flow and form gestures. A flow gesture could be a continuous gesture, where it progresses over a period of time or series of moments of time. The form gesture can be defined by determining whether the gesture follows a distinct path (such as scrolling a webpage based on position of words) or if it is based on a pose. This research uses the flow and form gestures as a guide to develop our own discrete and continuous gestures to allow the user a range of possibilities.

Hand gesture interaction should be simple enough to understand, while distinct enough so that the user understands which gesture has occurred. For example, uWave is an interactive application using gestures for various mobile devices that have a very small custom gesture recognition system to allow maximum space on the device [Liu09]. We expand this idea for maximum recognition rates while using only a small dataset.

This paper presents gesture recognition techniques that aim to allow better recognition of 2D and 3D gestures by extrapolating gesture sets using similar classifiers. We develop new gesture recognition algorithms that provide a seamless and effective natural interaction at various distances and screen resolutions. The contribution of our paper is as follows.

• New gesture recognition algorithms for fingertip interactions. The gesture pattern recognitions are identified in a simpler and faster way than the available techniques that use databases to store gesture templates for matching, such as [Ren11].

• An expansion of a 2D gesture recognition system [Vat12] into 3D, based on utilising LeapMotion device as input for the gesture recognition system.

• An evaluation of the developed system in terms of user experience and its effectiveness.
2. RELATED WORK
Kinect devices have been useful for medical practices for doctors and staff to interact with patient information without the requirement of the typical mouse and keyboard and the more inaccurate voice recognition [Ebe13]. Using third party libraries such as OpenNI [Pri16] and Libfreenect [Ope16] they were able to implement finger gestures into the OsiriX system [Ebe13]. This was achieved by taking the Kinect depth image, collecting the closest objects to the sensor then approximating the hand and fingers based on this blob. Once the hand and fingers have been recognised from the blob, each point around the hand is recorded and over time is checked with a database of other hands already recorded. However, the use of the Kinect V1 in [Ebe13] restricts the range of the interaction due to the limitations of the depth camera on these devices. The other major limitation of their system is the lack of explanation of the gestures to the user.

Another major work develops a new Kinect hand recognition system using the ‘golden’ energy function [Sha15]. It renders all possible poses of the hand and selects the pose, whose corresponding rendering best matches the input image while accounting for the prior probability of poses. The technique uses regions of interest (RoI) to determine the approximate hand position from the depth image stream and a learned pixel-wise classifier [Sho13]. When used with 3Gear [3Ge16] and LeapMotion device, this technique achieves a better percentage of 3D hand detection than those described previously. This system requires extremely large FingerPaint datasets of 3.2GB of storage space [Sha15] that could make portability and memory management an issue. High memory latency and a high end GPU are required when accessing the dataset in the memory in real time. In addition, the inability to work with both hands and the lack of a gesture recognition system for fingers could limit the utilisation.

Tang [Tan11] introduced a method for identifying grasping and pointing gestures in which a person’s hand model was estimated based on a skeletal tracker. This is limited in terms of tracking resolution and inability to track at a close distance. Chen and Wong introduced an interactive sand art drawing using Kinect [Che14]. Four key gestures were detected by the system, including sing-point finger for single point erosion, single splicing and leaking, V-shape 2 fingers for pinch spilling and pinch erosion. Lee and Tanaka used databases for fingertips and hand shapes to enable gesture cognition with any finger in the palm as well as two fingers (thumb and index finger) [Lee13]. The interaction techniques were applied to sample applications for finger painting and mouse controlling. Song et al proposed an algorithm for gesture recognition algorithm based on depth information from a Kinect device [Son13]. Cook et al also introduced a real-time finger-gesture interaction system using Kinect v2 that identifies finger gestures at close range [Coo15]. However, vision-based systems are often limited in terms of accuracy, occlusion and inconsistency when changing the environment, such as dark light and rough background.

3. GESTURE RECOGNITION
Our gesture recognition system was developed based on gestures as point clouds approach [Vat12], to address the problems identified in Section 2. The Point-Cloud Recogniser (SP) is a gesture recognition system designed for quick and simple recognition of two dimensional gestures from a user’s input. SP works by collecting a bunch of pre-determined points already created in the system, i.e. the database of gestures that the system can recognise. When ready to, it takes the users current points as an input to determine the closest matching set of user points to data points using a nearest neighbour classifier.

We expanded the recognition system from 2D to 3D that improved recognition accuracy and performance. The enhancement includes additional classifiers to the dataset to improve comparisons and collections of points by segmenting cloud stroke points based on certain parts of the hand and fingertips.

Gesture Recognition Systems
Gesture recognition systems that use SP include single stroke ($S$) and multi stroke ($N$) systems. A single stroke system can handle only one stroke on a canvas for comparisons. A multi stroke system can handle more than one stroke. $S$P uses the $S$ algorithm for nearest neighbour matching and gesture recognition, while also using $N$s algorithm for allowing multiple strokes to be recognised. The benefit of the dollar family gestures is how users can add their own variations to the data set to be used for future recognition [Wob07].

The uni-stroke recogniser ($S$) developed by [Wob07] is the first gesture recognition system developed in the $S$ family. Its implementation is similar to the $S$P system, which uses the nearest neighbour and Euclidean scoring systems. $S$1 is an extension of an existing recognition system called SHARK2 [Kri04]. It performs extremely well with recognising gestures even when given a low amount of training samples to compare user input.

The multi-stroke recogniser ($N$) is a solution to $S$1’s problem of not being able to use multiple strokes to determine a gesture [Ant10]. $N$ was designed so that the input of strokes would be stroke and direction invariant. This was achieved by recording all distinct directional behaviours of the gesture to compare the user data. $N$ has an immensely increased complexity by loading all of these permutations. This issue could
be improved by removing multiple stroke types and directional changes when comparing single stroke gestures [Ant10]. Protractor uses a closed-form template-matching method eliminating the simplicity and complexity of the Golden Section Search algorithm [Ant12].

We adopted multi-stroke recognition system that could handle multiple start and stop points. The system needs to be fast without the need to remember any permutations in the strokes as the stroke order is not important for our gesture recognition. This rules out $SN$ and $SN$-Protractors complex algorithms leaving $SP$. $SP$ does have one drawback with its implementation, where the point clouds are rotation variant. This means that each gesture is not rotated when comparing point clouds. To overcome this problem, when we developed the database we added gestures of different angles to the training set to compensate for this drawback.

**SP in a 3D world space (SP3D)**

Extending $SP$ into a 3D implementation was done by following the same algorithms in 3D space, such as Protractor [Kra11]. We utilise the practicality, simplicity and usability of the $SP$ algorithm, extending it to operate with three-dimensional gestures.

We take the existing method for gathering and assigning points with each gesture created and change the creation method depending on the data. Because the protractor recogniser takes the Euclidean distance between points in 2D to determine the distance, they take the Z position of the set of points when applicable. The result means that the distances between points when classifying gestures will be slightly more between 2D and 3D gestures because of the added axis.

The 3D centroid formula determines the centre of the 3D data points which is defined by equation 1. We used a 32-point sampling resolution (N) [Kra11] to define the insignificant change in accuracy. Translating the data requires the 3D centroid position to be equal to the subtraction of each of the data points with the centroid. The new translated data points will make the centroid be at position (0, 0, 0). This translating makes it possible to centre the data for recognition.

\[
Cx = \frac{\sum_{i=0}^{N-1} x_i}{N}, \quad Cy = \frac{\sum_{i=0}^{N-1} y_i}{N}, \quad Cz = \frac{\sum_{i=0}^{N-1} z_i}{N} \quad (1)
\]

Where Centroid $C = (Cx, Cy, Cz)$ and $N$ is the sampling resolution.

Resampling the data points is the most crucial of the pre-processing techniques. It requires multiple calculations to convert the data from any number of points to the sampling resolution of 32 that we want for 1:1 conversions between user data and gesture data. We extended the 2-dimensional method to create the linear interpolation (LERP) point as equation 2, where a new 3D point (P) was calculated by LERP point ($\bar{d}$), first point ($f$) and current point ($p$).

\[
\alpha = \frac{(1-D)}{D} \text{ where } D! = 0 \\
\bar{d} = \begin{cases} 
\alpha & \text{ if } \alpha > 0.0 \text{ and } \alpha < 1.0 \\
1.0 & \text{ if } \alpha \geq 1.0 \\
0.0 & \text{ if } \alpha \leq 0.0 
\end{cases}
\]

\[
P.x = (1.0 - \bar{d}) \times f.x + \bar{d} \times p.x \\
P.y = (1.0 - \bar{d}) \times f.y + \bar{d} \times p.y \\
P.z = (1.0 - \bar{d}) \times f.z + \bar{d} \times p.z \quad (2)
\]

**SP3D+**

While SP3D generally provides good gesture recognition in 3D, its effectiveness normally depends on datasets and user inputs. We added to the SP system a set of classifications and ordering the LeapMotion data so that each finger and palm position was its own stroke and followed its previous position. Our goal is to improve the 3D recognition system by eliminating the need to search all the gestures within the database. We also improved pre-processing gestures by assigning stroke IDs to point clouds to remove inaccuracies. The enhancements are as follows.

**Removing Redundant Point Clouds**

We limited the complexity of the gesture recognition by only selecting gestures that reach a certain classification. These classifications would remove the ambiguity of searching through all possible gestures and instead focus on the range. We developed three classifiers in the SP3D system. The first classifier determines whether the recorded gesture was in 3D or 2D. This classifier only worked when there was a 2D gesture being recognised. The second classifier is for identifying whether the gesture is a pose or not. A pose gesture features the input to contain very little movement to no movement whereas a normal gesture requires much more movement over a series of time. The third classifier determines which left or right hand that the gesture is used with. This implementation aims to remove ambiguity and noise when comparing gestures from the left hand that could increase recognition when using the right hand. For example, a left PEACE pose matches well with a right OK pose and vice versa.

**Assigning and Ordering Stroke IDs to the Hand**

SP was designed for a 2D drawing scenario that was inputted one stroke at a time and it did not take the stroke ID into consideration. While this is normally fine when the user draws the gesture one stroke at a time, it could be a problematic when recording
different strokes currently. This is because the system thinks the entire gesture is made of single strokes. SP does not take into consideration the stroke order, stroke direction and stroke permutations as in $\text{SN/SN-Protractor solutions}$ [Ant10, Kra11]. It implements the stroke system for pre-processing, resampling and calculating the path length for the gesture. We assigned the palm and the fingers with their own stroke IDs. The IDs of Palm, Thumb, Index finger, Middle finger, Ring finger, and Little finger were numbered 0 to 5 respectively. The order of stroke indexes of the hand and fingers was used to improve the matching rate between these point clouds. This improvement provides a closer approximation on how to interpret the data where inaccuracies can be reduced to produce a closer match to determine the correct gesture.

4. INTERACTION WITH LEAPMOTION – A CASE STUDY
The LeapMotion is a controllable device that tracks hand and finger movements using LEDs and infrared cameras. While the Kinect can track skeletons from long distances with its sensors, the LeapMotion is dedicated to tracking hands and fingertips with a shorter range and more accurate than the Kinect.

Capturing the 3D Point Clouds
In order for the LeapMotion to be recognised by the point cloud gesture recognition system, we created the training set that was used in the classifications of the gestures. The chosen data from the LeapMotion system to determining these gestures were the stabilised palm position and the stabilised tip position of all the fingertips. Other points such as the wrist and distal bone positions were not considered for the training set because these details were not used for the recognition system.

Environment Building
We used Unity 3D game engine to develop our interaction environment. Unity provides an excellent framework for developing tools and applications within its integrated development environment (IDE). Unity’s IDE allows for 2D or 3D applications with a variety of different tools that will improve a user’s experience with the system.

It is crucial for first time users to learn about the system interactively. We developed a tutorial system to illustrate all the different elements of our environment in such a way that is easy to follow and understand. The system also allows the user to revisit old lessons when required. Once completing the tutorial, we provide a showcase scene where users can collaborate and manipulate objects within the scene using these new abilities learnt.

Monsoon Minigame
We developed a simple minigame to help the users be familiar with the interaction using the LeapMotion. The game revolves around the user trying to catch as many boxes, barrels, orbs and traffic cones as they can. The objects are spawned above the user and trickle down every second. It is up to the user whether they want to hold these objects or to play around with them (See Figure 1). This minigame serves as an initial learning task for beginners and a challenge for the experts who want the highest score.

![Monsoon Minigame](image)

Figure 1. Mossoon Minigame monsoon state.

Tutorial System
The tutorial system was developed to help the users understand the systems. They included 2D drawing, 2D gesture recognition, moving the camera, 3D pose recognition and 3D gesture recognition. Each of these systems is also a state within the tutorial system that the user can cycle through. Each state has its own visual, written and interactive way of showing the user the current state.

2D Drawing
This state trains the user how to draw 2D objects on a canvas. The drawing system requires the use of the LeapMotion and a set of criteria needs to be met to begin drawing (see Figure 2). To begin with, the only hand that the drawing system recognises is the primary hand selected by the user in the first tutorial state. The index finger is chosen for drawing. When the user wants to stop drawing, they can either move all their fingers back from the sensor, or open their thumb out without the need of moving. If a user makes a mistake and wishes to undo the previous stroke on the canvas, they can do so by swiping right.

2D Gesture Recognition
The 2D gesture recognition scenes goal is to help the user with recognising 2D shapes. While this process could have been combined with the drawing state, our experiences show that learning to draw first with the added gesture recognition was too steep a learning curve for first time users. Once users are
familiar with the drawn shapes, they can move their hand by positioning all the fingers forward on the LeapMotion device. The system then classifies the gesture using $P$ and returns the best scoring point cloud for each gesture. The implemented gestures in this tutorial stage are Circle, Rectangle, Triangle and Cross. The user can create shapes and then grab, move or throw them away.

Moving the Camera
This tutorial follows the main principle where users can move around the play area with their secondary hand by closing it into a fist. This scene is used as a breaker from the 3D gesture recognition.

3D Pose Recognition
The 3D pose recognition scene teaches users how to hold their secondary hand when performing a pose. To perform a pose, the user positions their hand so that it forms a symbolic gesture and hold that pose until it is recognised. The Pose recognition system can use 4 different poses including the L Pose, the ROCK Pose, the OK Pose and the PEACE Pose (See Figure 3).

Poses are recognised within the gesture recognition system through the use of velocity within the LeapMotion device. We use this data to find the minimum x, y or z value from the hands and fingers velocity data. We then check if the hand has stopped moving with a velocity of under a minimum value. Once this occurs, the gesture recognition system records the position information from the fingers and palm for that frame. This process repeats until either the hand is moving quicker than the minimum velocity and our data points need to be reset, or the user holds their hand over the minimum number of frames required, 75 frames in our implementation.

Making users wait while performing a pose could be an issue if there is no hint or indication. To overcome this, a pose gesture indicator was presented showing the progression of a pose gesture until the pose recognition system can determine the pose.

3D Gesture Recognition
The 3D gesture recognition follows the 3D pose recognition state where we want to teach the user how to do gestures in the environment. To perform gestures, the user uses their secondary hand and makes a quick movement. As opposed to poses that require little to no movement, gestures requires a sudden movement that when slowed down is recognised as a gesture. We implemented two sample gesture recognitions in our system including SHAKE and GUN.

To recognise a gesture, the system gathers the same velocity data from the palm and fingers as with the pose recognition system but determines the maximum velocity from the x, y and z values instead. It then waits until the velocity from the palm or fingers is greater than the maximum velocity of 500 millimetres and then it starts recording the gesture. Once this happens, each frame is recorded until the hand or fingers velocity has fallen under 500 millimetres or the number of gesture frames is over our sampling resolution of 32 points. A gesture indicator was also created to assist the interaction.

Practice Systems
We developed two practice systems to complement the lessons taught in the LeapMotion tutorial environment. The first system is a target practice scene that uses 2D drawings to create objects for the user to fling around and 3D poses for altering those shapes properties. This scene also uses 3D gestures for users to interact with the environment as opposed to just the shapes. The second system is a Cave Painting system that emulates how users could use the 2D recognition system in a creative and fun way with an image matching game.

Target Practice System
The target practice system is the showcase scene for our LeapMotion environment. It contains a number of gestures in both 2D and 3D and offers an open

---

Figure 2. Tutorial state default template.

Figure 3. L Pose, ROCK Pose, OK Pose and PEACE Pose respectively.
sandbox where the user can use all these different systems together to interact with the environment. The interactable objects within the play area are cube walls and targets. Targets generate points based on how close an object gets to the centre from the users throw and a cube wall acts as a breakable barrier which users can break open by using multiple objects at once (see Figure 4).

The types of 3D Poses that our system can recognise are: L Pose this turns the gravity off for all created objects, OK Pose changes the colours of all newly created objects, ROCK Pose triples the current objects created and the PEACE Pose makes all the objects heavier/lighter. The 3D gestures that the Target Practice scene can also recognise are SHAK3 Gesture that shakes the camera around and the GUN Gesture that creates a bullet launched from the fingertips that explode on impact.

**Cave Painting**

The Cave Paintings goal is to closely match one of the 5 popular animals from the Australian outback (see Figure 5). The Bat and Turtle contain the fewest shapes; the Emu and Lizard are more complicated due to their curves and the Kangaroo is the most difficult one with both curves and difficult shapes. Users are required to trace the animal drawing using their finger as close as they can. The system gives the users feedback on how close they were to the drawing as well as acknowledge their performance. These messages do not have negative comments written on the drawing to provide an enthusiastic approach when trying to draw the animal.

5. **EVALUATION**

We compared the results of three different point cloud gesture recognition systems ($P$, $P3D$ and $P3D+\_$. Using the training set defined and created by using the program, we evaluated the performance (time complexity and the average recognition percentages) of the original 2D algorithm ($P$), the added 3D gesture recognition algorithm ($P3D$) and our improved 3D recognition algorithm ($P3D+$). The gesture set consists of 15 gestures ranging from iconic aboriginal animals, 2D shapes, 3D poses and 3D gestures. The results in these experiments were evaluated based two sample gesture databases.

The first database consists of all 15 gestures from the gesture set, from which each pose per hand has 4 angle variations that were split into normal, rotated forward, rotated left/right (based on what hand was used) and rotated back. Each gesture on each left- and right-hand has five variations. Each of the 2D animal gesture contains three similar variations while each 2D shape also has five variations in average per shape. Overall, this database totals to 28 poses and gestures recorded (300kb) and 35 animal and shape drawings (600kb).

The second database expands the 3D gesture set by doubling the number of variations per hand to 10 each. The 3D poses also receive an increased number of variations per hand, from five to six. We also exclude all 2D gestures to focus on 3D recognition. To create unbiased results, the classification of the results uses the 3D poses and gestures from one database as the gesture/pose input to compare point clouds and determine the minimum distance by using another training set.

We initially used the scoring equation defined in [Wob07, Ant10]. However, this scoring method produces scores within the 95%-99% margin with very few scores ranging outside this segment. Our implementation requires the scores to range based on our observed minimum distances for the correct and incorrect gestures. To overcome this limitation, the scores were calculated using a polynomial formula to extrapolate the data explained above into a curve to map the distance data to the following percentage values, particularly $0.5 = 99\%$, $0.9 = 90\%$, $1.1 = 85\%$, $1.3 = 80\%$, $1.5 = 75\%$, $3.5 = 20\%$, and $4 = 0\%$.

We do not consider the average recognition rate for $P$ on 2D gestures as the recognition average has already been conducted by [Ant12]. We test $P$'s ability to recognise 3D gestures versus $P3D$ recognition system using both databases.
Comparing $P$ to $P_3D$

First Dataset

From the results on the first dataset (see Figure 6), we can see a clear indication that $P$ could not determine any differences between 3D and 2D data. It is a surprise that the recognition rate in the L pose, $P$ proved to be more efficient when compared to $P_3D$ (84% Range CI = [81, 87] to 77% CI = [74, 80]). However, the recognition rates for other gestures were higher in $P_3D$ in comparison to $P$ particularly the L pose. There is no clear indication from the noise of the other gestures like Bat 90% CI = [87, 93], Circle 89% CI = [87, 91], Kangaroo 89% CI = [85, 93], Lizard 89% CI = [86, 92], Rectangle 91% CI = [88, 94] that the L pose was the most recognised gesture. All other poses and gestures have significantly decreased average recognition rates for the correct gesture with high recognition rates for the wrong gestures. With the ROCK pose, $P$ does have a high average recognition rate of 91% CI = [86, 96], but is still beaten by $P_3D$s average of 95% CI = [93, 97]. This indicates our 3D implementation works better than the traditional 2D system.

Second Dataset

From the second dataset (see Figure 7) with a larger 3D database, $P$ performs miserably when determining the GUN gesture with an average recognition rate (< 50%) as well as an extremely low average recognition rate for SHAKE gesture (< 5% recognition mark). $P_3D$s performs much better above the 95% recognition average, for example the SHAKE Left Hand (96% CI = [94, 98]), Right Hand (98% CI = [97, 99]) and GUN Left Hand (98% CI = [97, 99]) and GUN Right Hand (100%). When presented with a larger L pose database, the $P$ recognition average actually performs better than $P_3D$ with the Left Hand scoring an excellent 90% (CI = [89, 91]) versus $P_3D$s 85% (CI = [83, 87]) recognition average and the Right Hand achieving similar results with a 83% (CI = [76, 90]) average compared to $P_3D$s 78% (CI = [72, 84]). This means that while the $P$ system performs worse on all gestures it has the ability to perform well or better than $P_3D$ on pose recognition.

Comparing $P_3D$ to $P_3D+$

With the improvements made to $P_3D+$, we evaluate whether our new $P_3D+$ performed better than the original $P_3D$. These evaluations follow the above comparisons, and T-value tests are used to determine if the improvements are statistically significant (alpha level of .05 for all statistical tests).

First Dataset

Figure 6 shows the GUN gesture has a decreased recognition rate from $P_3D$s 98% (CI = [97, 99]) to $P_3D+ 95% (CI = [92, 98]) but there is no statistical significant difference between these two systems.
respectively - $t(8)=1.71, p=0.09$. This result means that while SP3D+ recognition average is lower than SP3D, there is not enough evidence to class both sets of data as different. With the PEACE Pose, we found that there was a significant difference in recognition averages for $SP3D$ 88% (CI = [84, 92]) and $SP3D+$ 96% (CI = [93, 99]) $t(22)=3.01, p<0.01$. This result suggests that the improvements made to increase the recognition for the PEACE pose have increased the average enough to be statistically significant.

Second Dataset
Figure 7 also indicates that our hypothesis of the best-case scenario is apparent in the GUN (Left/Right) hand. For the Left Handed GUN gesture, the $SP3D$ Right Handed GUN recognition average is almost the same as the Left Handed average (99% CI = [98, 100]) while the $SP3D+$ system has a lower percentage of 98% (CI = [96, 100]) - $t(8)=0.59, p = 0.57$. This means that the $SP3D+$ system is missing the best recognisable gun gesture and that is lowering its average. With the Right Handed L pose we can also determine that the recognition average is not significant between these systems while $SP3D+$ has a significantly increased recognition rate when compared to $SP3D$ (92% CI = [82, 100]) and 78% CI = [72, 84]) respectfully - $t(8)=1.00, p = 0.35$. For the Left Handed L pose the difference is extremely noticeable. For the $SP3D$ system, the average recognition rate is around 85% CI = [82, 88]). The $SP3D+$ system achieves a higher recognition rate of 98% (CI = [95, 100]) with a significant difference between the 3D and 3D+ systems $t(6)=5.97, p < 0.01$. This shows that when the user performs an L pose, the $SP3D+$ system is going to recognise that pose easier.

Discussion
When differentiating $SP$ with $SP3D$, the assumption was that $SP3D$ would outperform $SP$. With the majority of gestures, $SP3D$ recognises the 3D point cloud with excellent gesture recognition average while $SP$ has high averages. The L Pose interestingly with the small database and the L and Rock Poses in the large database, the $SP$ gesture recognition system perform better than the 3D system.

When comparing $SP3D$ and $SP3D+$, the improved gesture recognition system hypothetically yields slightly lower results based on the limitations of the training data gathered for testing. Our experiment shows that with some gestures, it actually increased the recognition rate by a small margin of 4.55%. The Left Hand L pose was the best result that achieved an increased recognition average of 13.17%. While this improvement increased the recognition average, we can claim that the confidence interval for the $SP3D+$ gesture recognition average falls way out of the more condensed $SP3D$ versions interval as $SP3D$ factors in all gestures and gets the best-case scenario for each pose/gesture. However, the GUN gesture and the OK Pose did follow our hypothesis of having a smaller recognition rate compared to the traditional 3D gesture recognition. This is because of the small difference between left and right hand GUN gestures.

User Experiences
We demonstrated the system to several people during various events hosted by the Western Sydney University. While no formal questionnaires were given, we have documented the difficulties and differences between users who have used the system for the first time and some who have had experience with this device before. The users were a variety of ages ranging from primary school children, high school students, university undergraduates and some academic researchers. The users mostly inciated that they never used the LeapMotion system before.

From those who have no prior experience with the LeapMotion it was clearly that they found it difficult to first locate the LeapMotion system and use it properly. The main problem was the simplicity in the LeapMotions design causing users to not believe that the system could perform 3D hand recognition. Another issue was users who would immediately try to move their hand as close to the sensor as possible. While the LeapMotion can detect hands from a short distance, if the hands are too close to the IR cameras they could not distinguish the hands properly. Once instructed to move their hands upward, users understood the distance required for recognition and rarely brought their hands too close to the sensor again. Users were presented with either the default LotsOfBlocks demo or the Monsoon minigame developed for the first time users.

For the users who were presented with the Monsoon minigame, comments were made about what they were supposed to do while the minigame was playing. As the premise for the scene was to catch as many objects as possible, users found that the LeapMotion could not track their hands very well when they were cupped together. Some users decided to ignore grabbing the objects but rather tried to fling the objects around and as far as they could to see who could get the furthest.

The overall consensus with most individuals who used these demos was overwhelmingly positive. While some had seen the LeapMotion technology before or were not enthusiastic with the devices capabilities, the majority enjoyed using the tracking system.

6. CONCLUSIONS
In this paper, we have presented gesture recognition techniques that allowed recognition of both 2D and 3D gestures using point cloud gesture recognition. These techniques extrapolate gesture sets using
similar classifiers to recognise when to start looking for a gesture. We implemented tools that collected gesture data for recognition and processing. We also developed new 2D and 3D interactive environments that acted as a visual representation of the data.

We enhanced a 2D point cloud gesture recognition system into a 3D gesture recognition system that supports the data points from the LeapMotions hand, palm and fingers. We implemented four poses and two gestures to demonstrate the effectiveness of the new 3D gesture recognitions. We used a small database system for our gesture set in comparison to large database in existing systems.

Our experimental results showed that the 3D system outperformed the traditional 2D system in most cases as well as some small improvements on the $P3D+$ in comparison to the original $P3D$.
